

Module 3: Machine Learning Part 1 Feature Engineering

Agenda

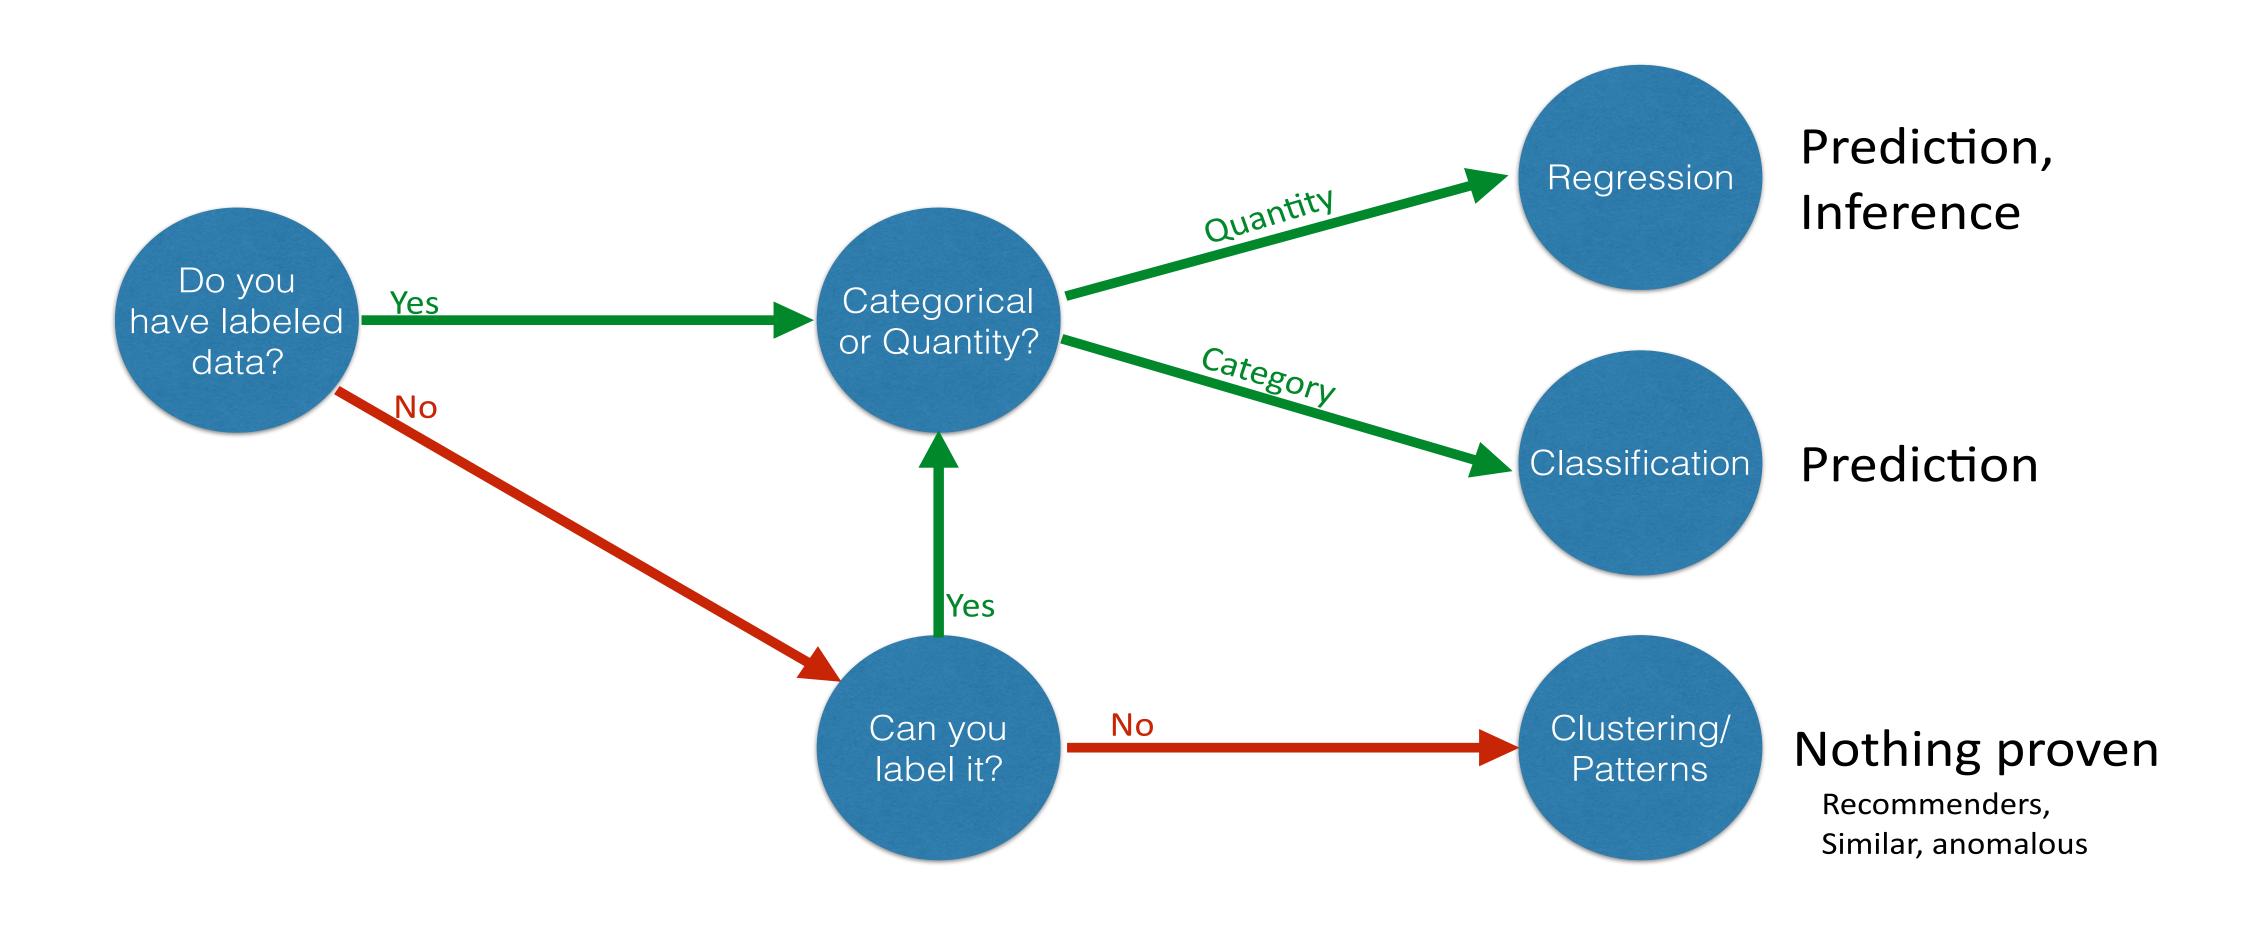

- Feature Selection & Engineering
- Math free overview of classification models
- Evaluating Model Performance
- Improving model performance

Machine Learning Process

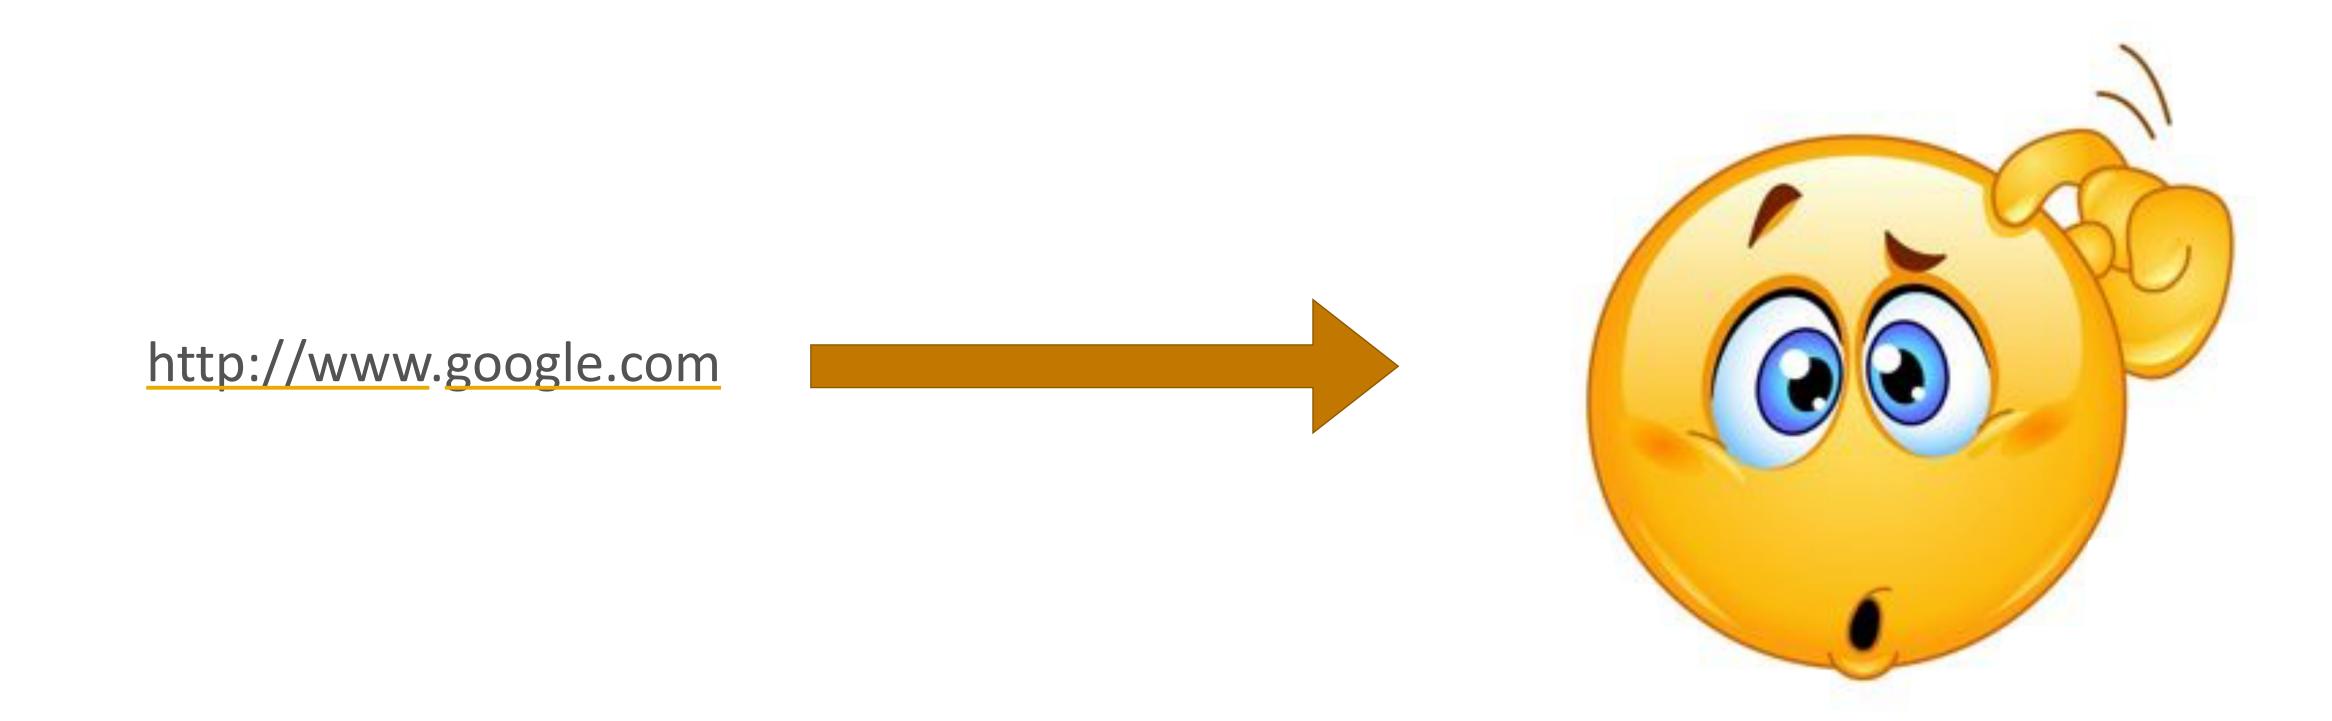

Machine Learning Terms

- **Features:** The mathematical representation of the original data. The features are the columns in your data set. Since the features will be a matrix, the are often written as X.
- Observations: The rows of your feature set.
- **Target:** The variable that you are trying to predict. Often represented as y.

Features

Features

http://www.google.com

domain_length	vowel_count	digit_count
6	3	0

Representation of URL Knowledge

- Come up with a representation/set of knowledge that has enough complexity to accurately describe the problem for the computer
- Knowledge here does not mean hard-coded knowledge or formal set of rules
- The computer rather uses the knowledge we provide to extract patterns and acquire own knowledge
- We should provide knowledge about reality that has high variance about the problem it describes (e.g. a feature that is high when it rains and low when it's sunshine)

https://www.google.com/search? q=URL&source=Inms&tbm=isch&sa=X&ved=OahUKEwjcl6ut-IDUAhVEPCYKHdJGDsYQ_AUIDCgD&biw=1215&bih=652

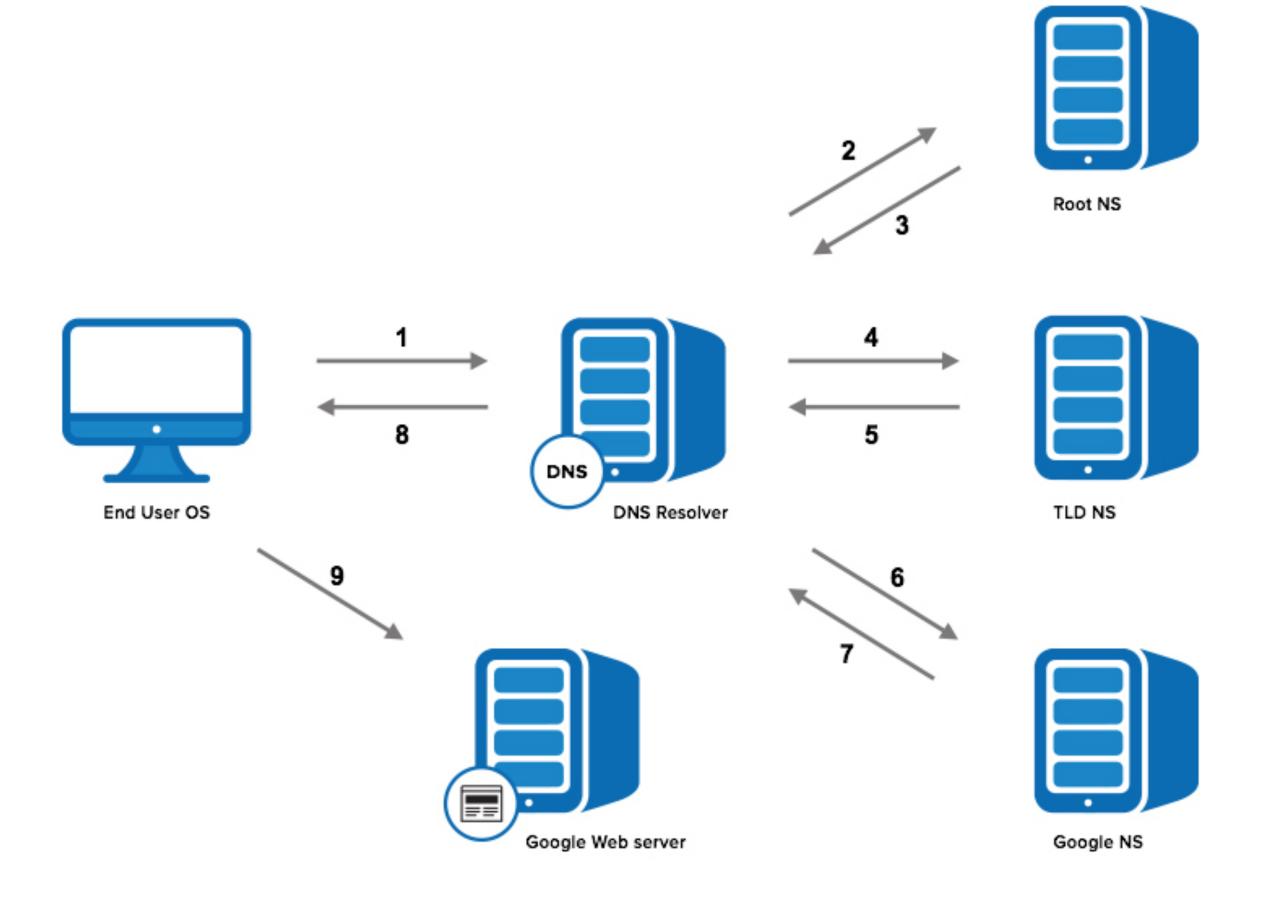

https://	protocol
WWW	subdomain
google.com	zone apex
google	domain
.com	top-level-domain (tld)
/search?q=URL	path

DNS 101

- Domain Name Service (DNS) resolves domain names to IP addresses (like a phone book)
- Domain Registrars: authority that signs unique domain names (GoDaddy, BlueGtaor)
- **State of Authority** (SOA): Contains for example name of server for zone, administrator of zone, default time-to-live (ttl = time a DNS record is cached), seconds of secondary name server should wait before checking for updates
- Root Zone controlled by Internet Assigned Numbers Authority (IANA)
- Name Servers (NS Records): used by tld servers to direct traffic to DNS server (which
 contains authoritative DNS records)
- A records (part of DNS record): "A" stands for IP Address
- **CNAME** (part of DNS record): resolves one domain name to another
- Autonomous System (AS) and Border gateway Protocol (BGP) info

Python libraries: python-whois, dnspython, tldextract, ipaddress

DNS Flow

What makes them different?

URL BlockList

Malicious URL Detection Features (Literature)

- 1. **BlackList Features**: BlackLists suffer from a high false negative rate, but can still be useful as machine learning feature.
- 2. **Lexical Features**: Capture the property that malicious URLs tend to "look different" from benign URLs. **Contextual information** such as the length of the URL, number of digits, lengths of different parts, entropy of domain name.
- 3. **Host-based Features**: Properties of web site host. **"Where"** the site is hosted, **"who" owns it** and **"how" it is managed**. API queries are needed (WHOIS, DNS records). Examples: Date of registration, the geolocations, autonomous system (AS) number, connection speed or time-to-live (TTL).
- 4. **Content-based Features**: Less commonly used feature as it requires **execution of web-page**. Can be not only be not safe, but also increases the computational cost. Examples: HTML or JavaScript based.

Domain Generating Algorithm (DGA) Detection

What is DGA?

- Domain Generating Algorithms (DGA) are algorithms which generate pseudo-random domains that are used for infected machines to communicate with the controller.
- The seeds on both the victim and command server are synchronized
- First seen with the Conficker worm.
- "Hello world" of cyber machine learning.

Preparation In Class Exercise ML Feature Engineering

Lexical Features

- 1. Length of URL
- 2. Length of domain
- 3. Count of digits
- 4. Entropy of domain
- 5. Position (or index) of the first digit
- 6. Bag-of-words for tld, domain and path parts of the URL

Host-based Features

- 1. Time delta between today's date and creation date
- 2.Check if it is an IP address

Data Set (Features and Target)

	url	isMalicious	domain	created

45022	1	0	23	11	7	3.277613	13	0	0	0	 0	0

Bag-of-Words

- Bag-of-words model: (Frequency of) occurrence of each word is used as a feature
- Sklearn's CountVectorizer: Convert a collection of text documents to a matrix of token counts

```
Simple Example: Imposing a vocabulary of top_tlds=['.com', '.de', '.uk']

CountVectorizer_tlds = CountVectorizer(analyzer='word', vocabulary=top_tlds)

CountVectorizer_tlds = CountVectorizer_tlds.fit(tlds)

matrix tlds = CountVectorizer tlds.transform(tlds)
```

Bag-of-words model fitting

URL string
google.ru
facebook.com
google.de

'.com'	'.de'	'.uk'
0	0	0
1	0	0
0	1	0

Preprocessing - an Art Work!

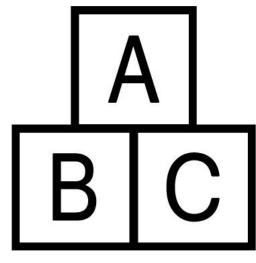

- Imputing missing values
- Scaling/Normalization
- One-Hot Encoding (Encoding categorical features)
- Embedding (e.g. word2vec)
- Binarizing (e.g. needed for Deep Learning multi-class target vector encoding)
- Encoding strings as int
- Dimensionality Reduction (e.g. PCA)
- Augmentation (e.g. tild/zoom images)
- Feature selection based on classifier
- Variance threshold

Imputing Missing Values

```
# using the most_frequent value
df['src_bytes'] = df['src_bytes'].fillna
(df['src_bytes'].value_counts().index[0])

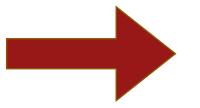

# using the mean value
df['dst_bytes'] = df['dst_bytes'].fillna(df['dst_bytes'].mean())
```

One Hot Encoding

Color
Red
Red
Blue
Green
Yellow
Red

One Hot Encoding

4 Categories

4 Columns with 1 when Category is True and delete original column!

Color
Red
Red
Blue
Green
Yellow
Red

Color_Red	Color_Blue	Color_Yellow	Color_Green
1	0	0	0
1	0	0	0
0	1	0	0
0	0	0	1
0	0	1	0
1	0	0	0

One Hot Encoding

```
colors = ['Red', 'Red', 'Blue', 'Green', 'Yellow', 'Red']
series_data = pd.Series( colors )
pd.get_dummies( series_data )

# df scenario
df=pd.get_dummies(df, prefix=None, prefix_sep='_',
dummy_na=False, columns=['protocol_type','flag'],
sparse=False)
```

Better way: Feature Engine

- Feature Engine is a module which helps automate the complexities of feature engineering.
 - Missing Value Imputation
 - One Hot Encoding
 - Outlier Capping
 - More...
- Docs here: https://feature-engine.readthedocs.io/en/latest/
- Blog post: https://thedataist.com/when-categorical-data-goes-wrong/

Feature Engine

```
from feature engine import categorical encoders as ce
import pandas as pd
# set up the encoder
encoder = ce.OneHotCategoricalEncoder(
    top categories=3,
    drop last=False)
# fit the encoder
encoder.fit(df)
encoder.transform(df)
```

Encoding Strings as Integers

```
PROBE = ['portsweep.', 'satan.', 'nmap.', 'ipsweep.']
df = df.replace(to replace = PROBE, value=1)
```

Feature Scaling

When you're creating a scaling object, you should first "fit" it to the training data, then transform both the training and testing data using the "fit" scaler.

If you try to fit the training and testing data separately, you will

Standard Scaling

$$zscore(x_i) = \frac{x_i - \mu}{\sigma}$$

```
scaled_feature = (feature - column_mean) / standard_deviation
```

Standard Scaling

$$zscore(x_i) = \frac{x_i - \mu}{\sigma}$$

from sklearn.preprocessing import StandardScaler
scaler = StandardScaler()
scaler.fit(features)
features_scaled = scaler.transform(features)
or
features scaled = scaler.fit transform(features)

Standard Scaling

```
scaled values:
original values:
                             [[1.2247 -0.8627 -1.2247]
 [[ 0.9 0.1 40.]
                             [-1.2247 -0.5392 0.
[ 0.3 0.2 50.]
[ 0.6 0.8 60.]]
                             [ 0. 1.4018 1.2247]]
                            Means of scaled data, per column:
Mean of each column:
                             [ 0. -0. 0.]
[ 0.6 0.3667 50.]
                            SD's of scaled data, per column:
SD of each column:
 [ 0.2449 0.3091 8.165 ] [ 1. 1. 1.]
```

Notice that the mean of standard scaled data is zero and the StdDev is 1.

Min/Max Scaling

$$X_{norm} = \frac{X - X_{min}}{X_{max} - X_{min}}$$

```
normed_feature = (feature - col_min) / (col_max - col_min)
```

Min/Max Scaling

```
from sklearn.preprocessing import MinMaxScaler
minmax = MinMaxScaler()

minmax.fit(features)
features_scaled_minmax = minmax.transform(features)

or

features_scaled_minmax = minmax.fit_transform(features)
```

Min/Max Scaling

```
original values:
                     scaled values:
[[ 0.9 0.1 40.]
                     [[ 1. 0. ]
[ 0.3 0.2 50.]
                [ 0. 0.1429 0.5 ]
[ 0.6 0.8 60.]]
                    [ 0.5 1. 1.
Mean of each column:
                     Means of scaled data, per column:
                     [ 0.5 0.381 0.5 ]
[ 0.6 0.3667 50.]
                     SD's of scaled data, per column:
SD of each column:
```

Dealing with Imbalanced Classes

Dealing with Imbalanced Classes

- A lot of real-world security data will have very imbalanced targets.
- Fortunately, there is a library called imbalanced-learn which can assist.
- Imbalanced-learn provides a series of options to resample the data so that you have more balanced classes
- Docs available here: http://imbalanced-learn.org/

Dealing with Imbalanced Classes

```
from imblearn.over_sampling import
RandomOverSampler
ros = RandomOverSampler(random_state=0)
X resampled, y resampled = ros.fit resample(X, y)
```

Selecting Features

Should we use all of them?

How do we know which features to use and which to discard?

Before using automation, you should remove:

- Unnecessary features that are uninformative or repetitive
- Irrelevant features
- Duplicate observations

Selects k features according to the highest score

```
best_features = SelectKBest(score_func=chi2,k=3).fit_transform(features,target)
```

Selects all features above a given threshold in the scoring function

```
best_features =
SelectPercentile(score_func=chi2,percentile=3).fit_transform(features,target)
```

Available Scoring Functions:

- For regression: f_regression, mutual_info_regression
- For classification: chi2, f_classif, mutual_info_classif

http://scikit-learn.org/stable/modules/generated/sklearn.feature_selection.SelectKBest.html

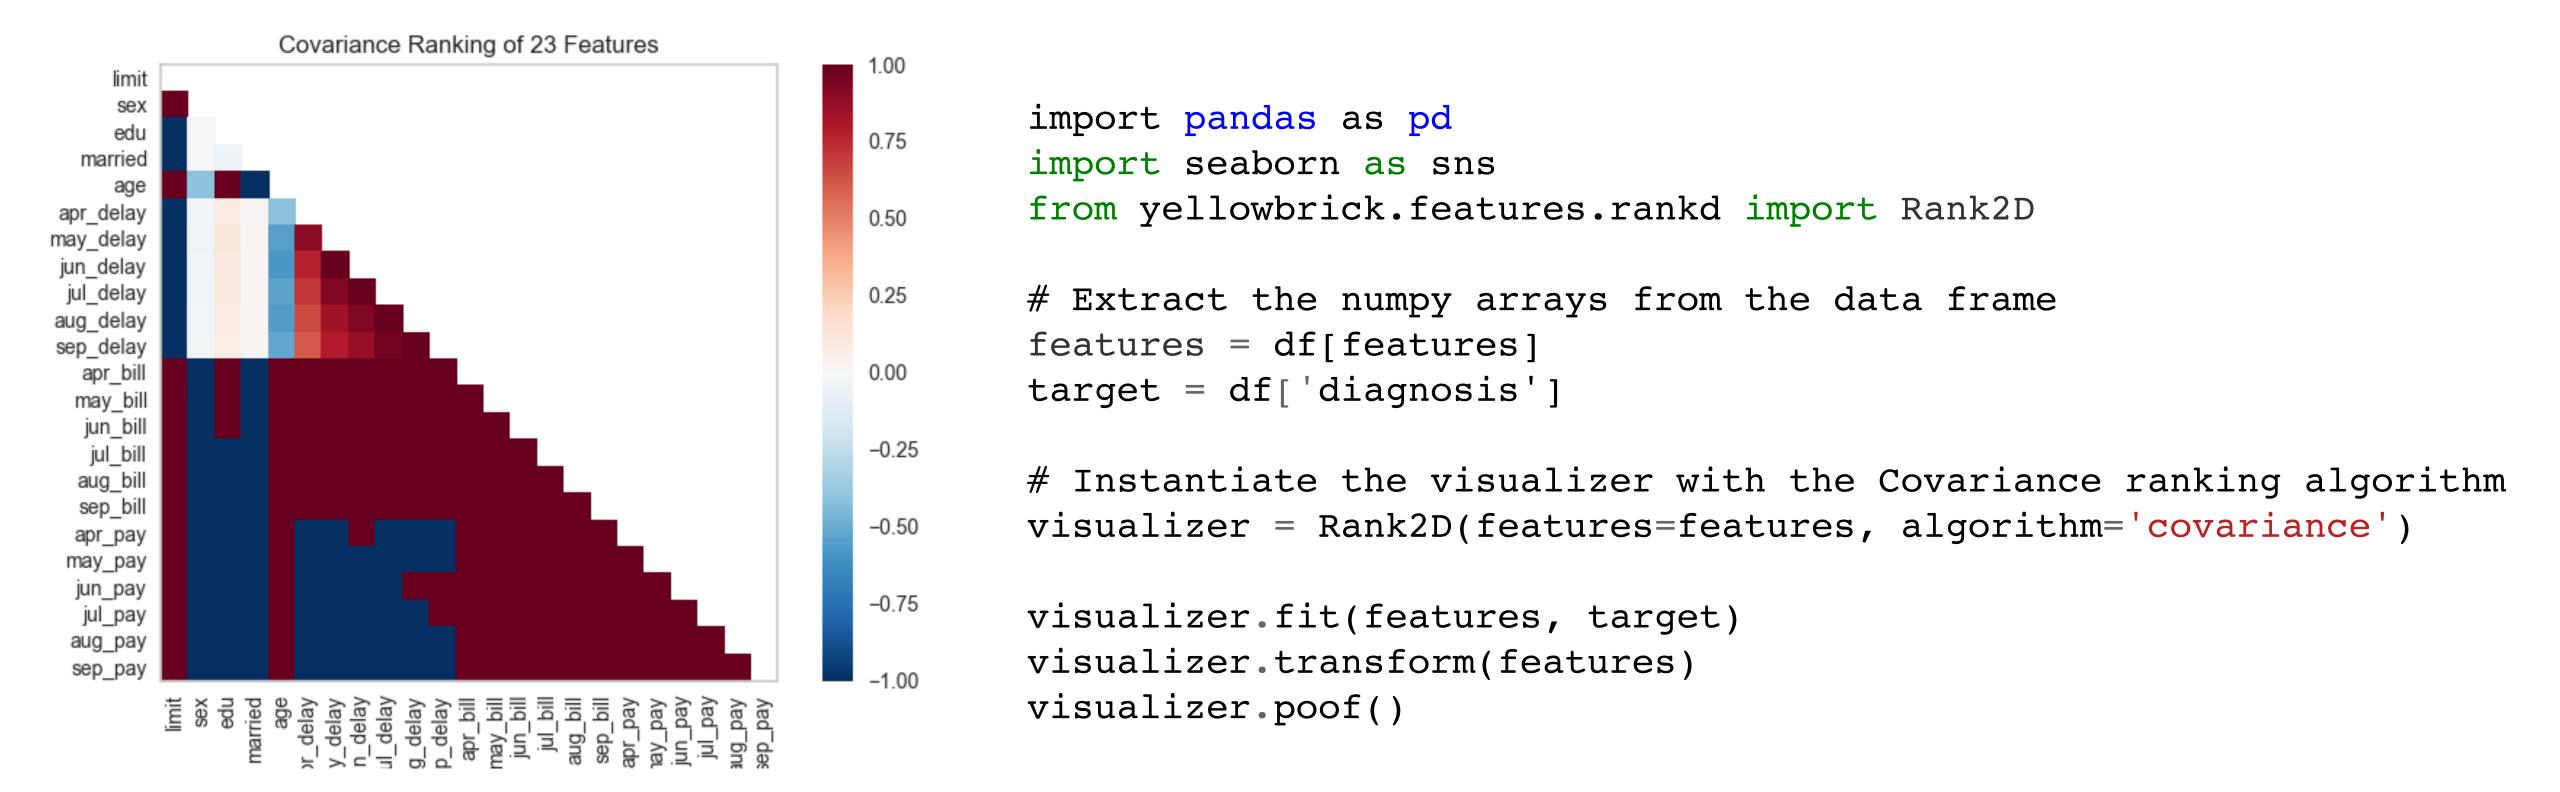

http://scikit-learn.org/stable/modules/feature_selection.html#univariate-feature-selection

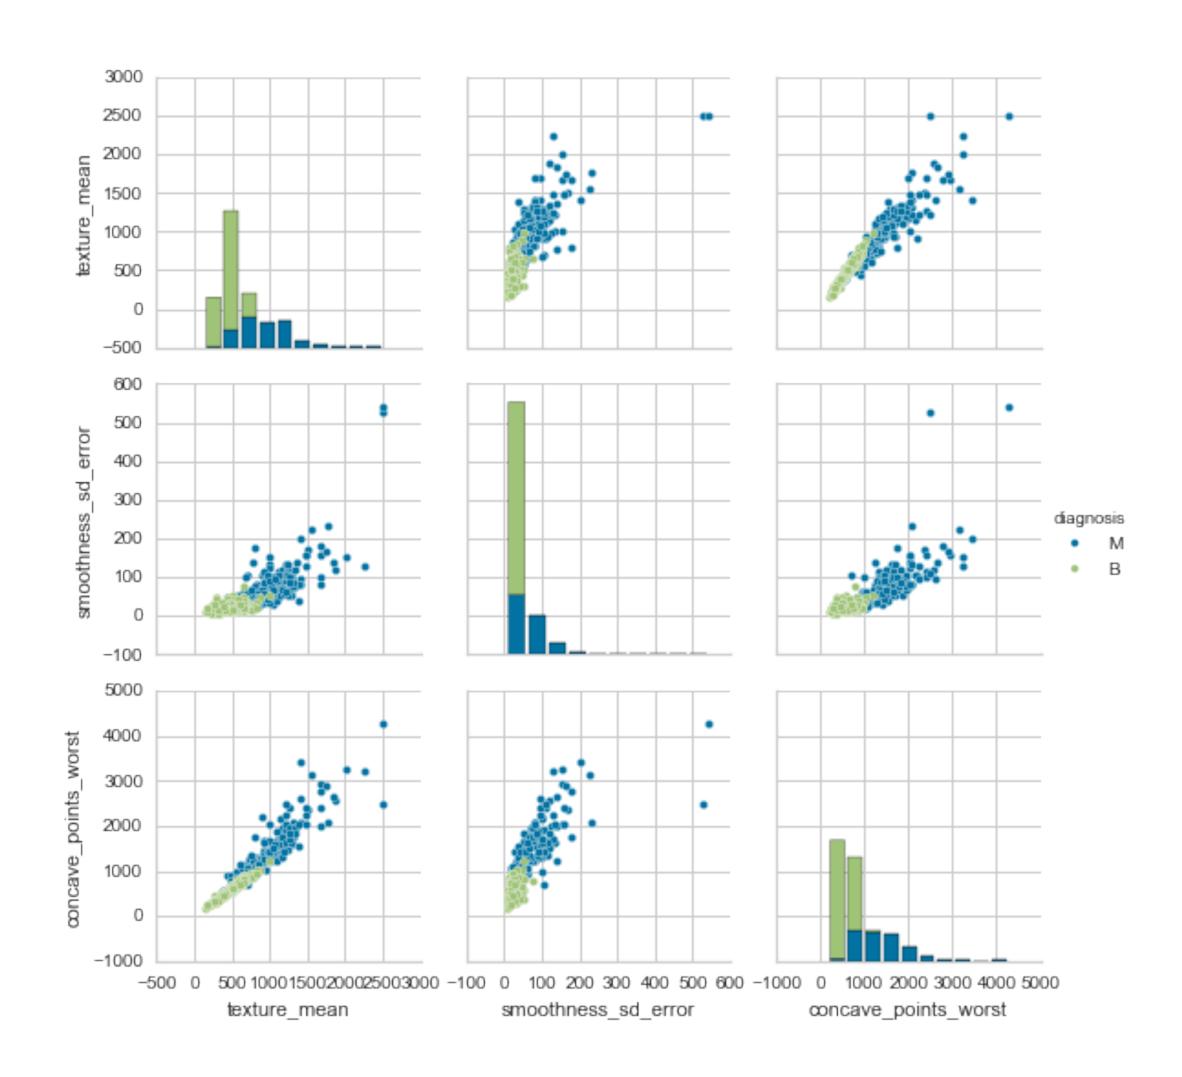

How do we know which features to use and which to discard?

Visualize Them!!

Introducing Yellowbrick and scikitplot

import seaborn as sns
sns.pairplot(<features>, hue='<target>')

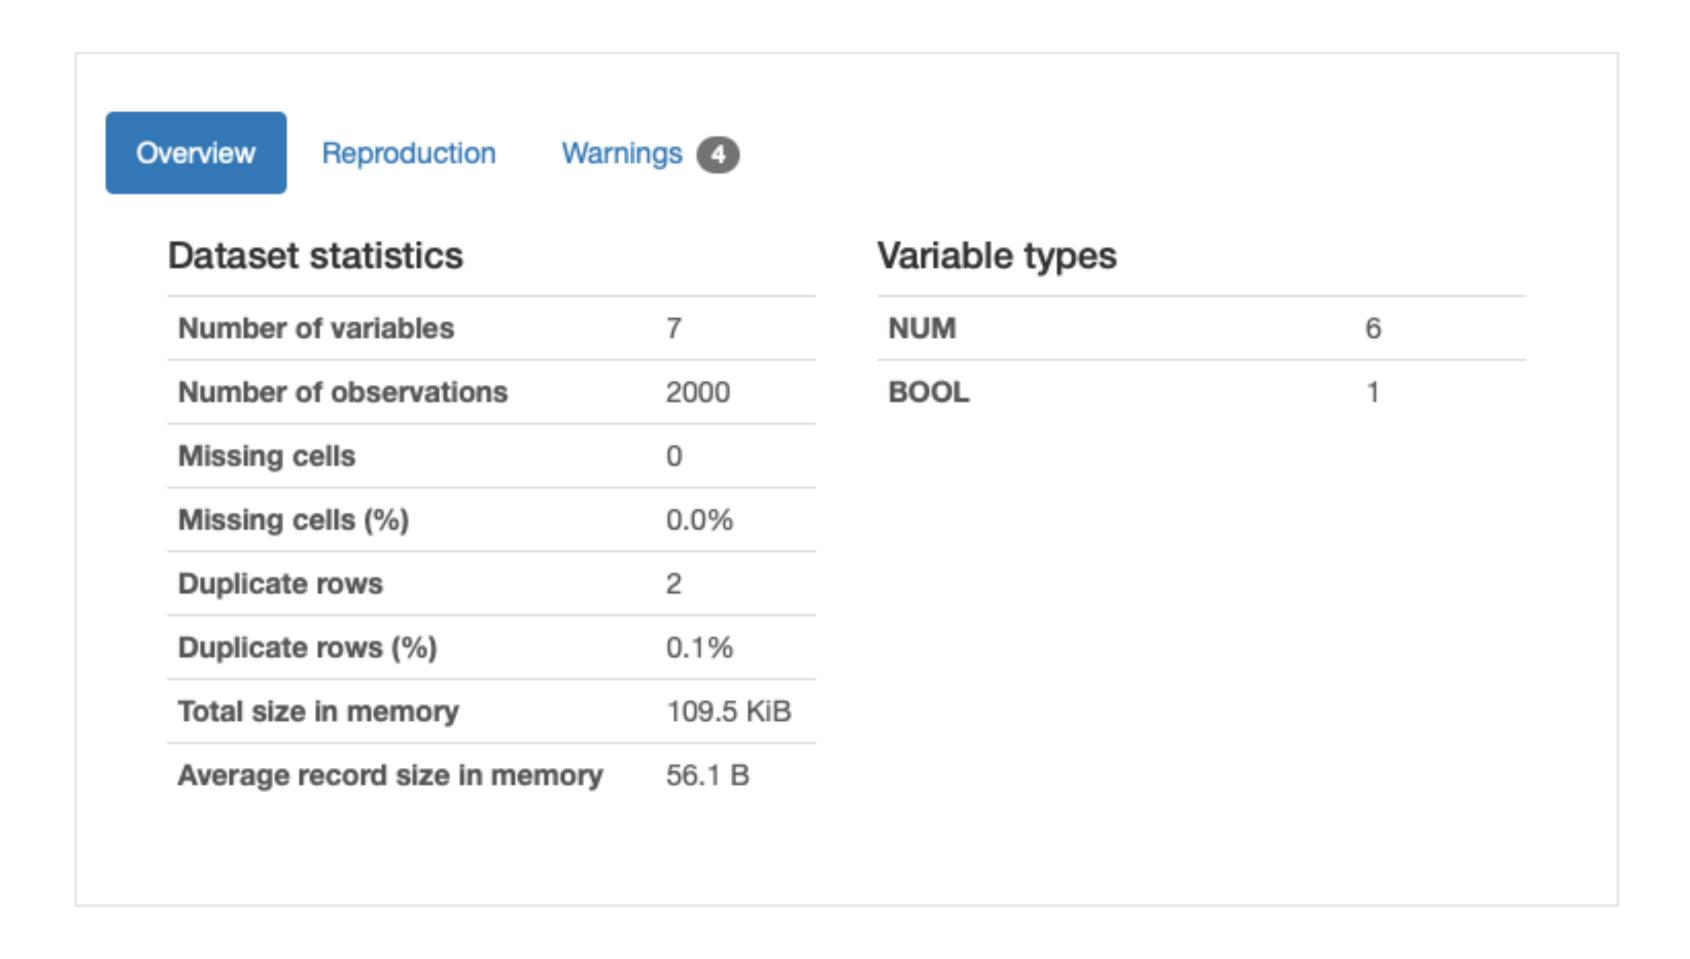

```
from yellowbrick.features.radviz import RadViz
...
visualizer = RadViz(classes=<target classes>, features = <features>)
visualizer.fit(features, target)
visualizer.transform(features)
visualizer.poof()
```

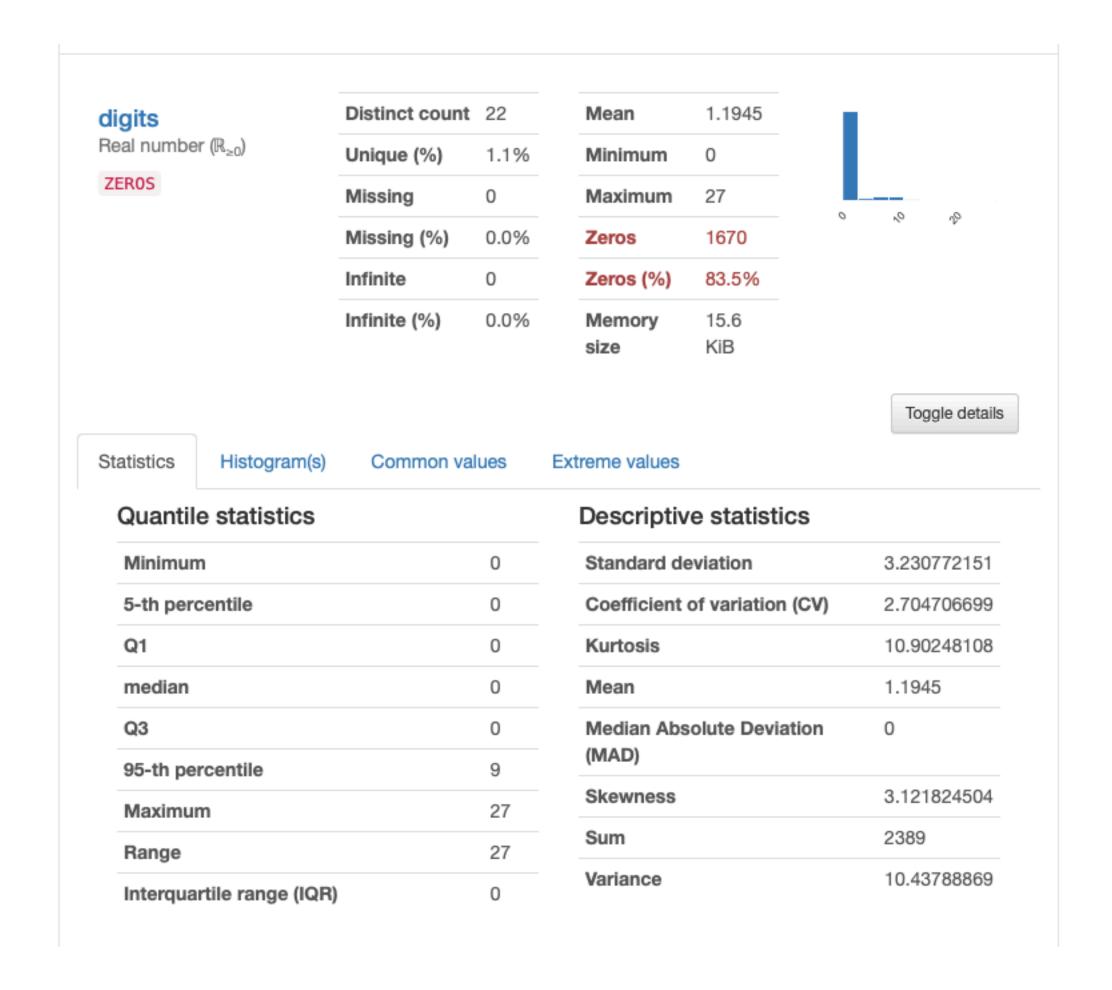

Do it all at once!

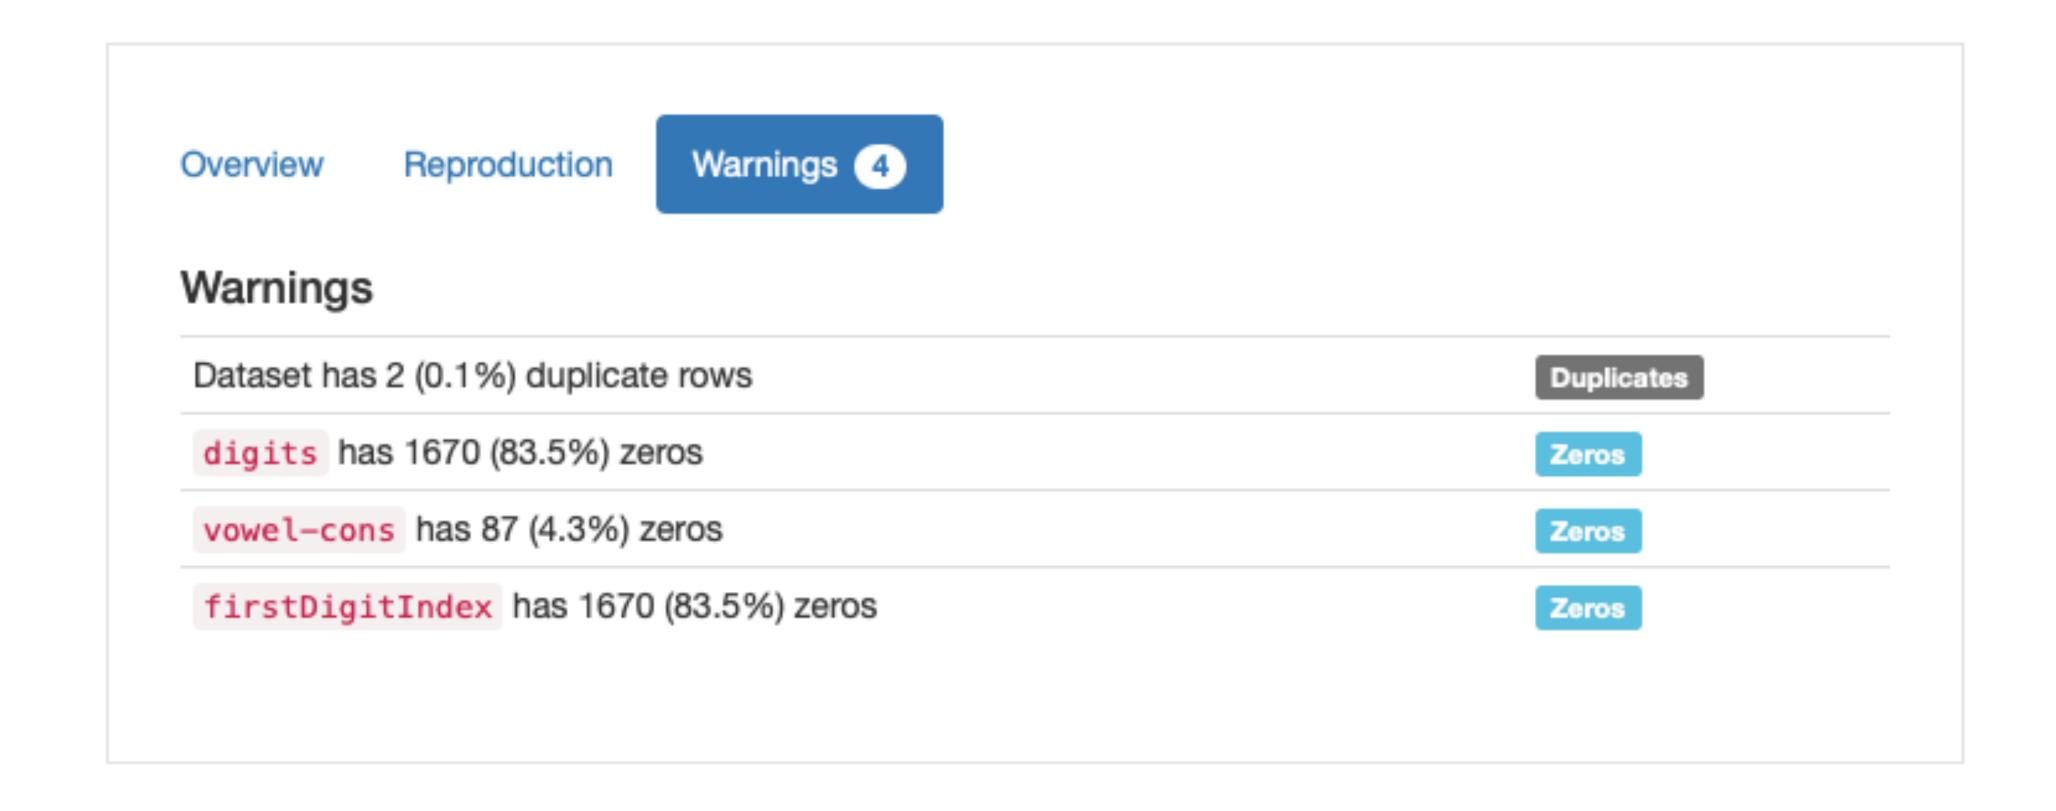

- YData-Profiling (Formerly Pandas-Profiling) is a module which can generate very thorough summaries of your datasets.
- Simple to use, but computationally intense...

```
from ydata_profiling import ProfileReport
profile = ProfileReport(df, title='DGA Feature Profiling Report')
profile
```

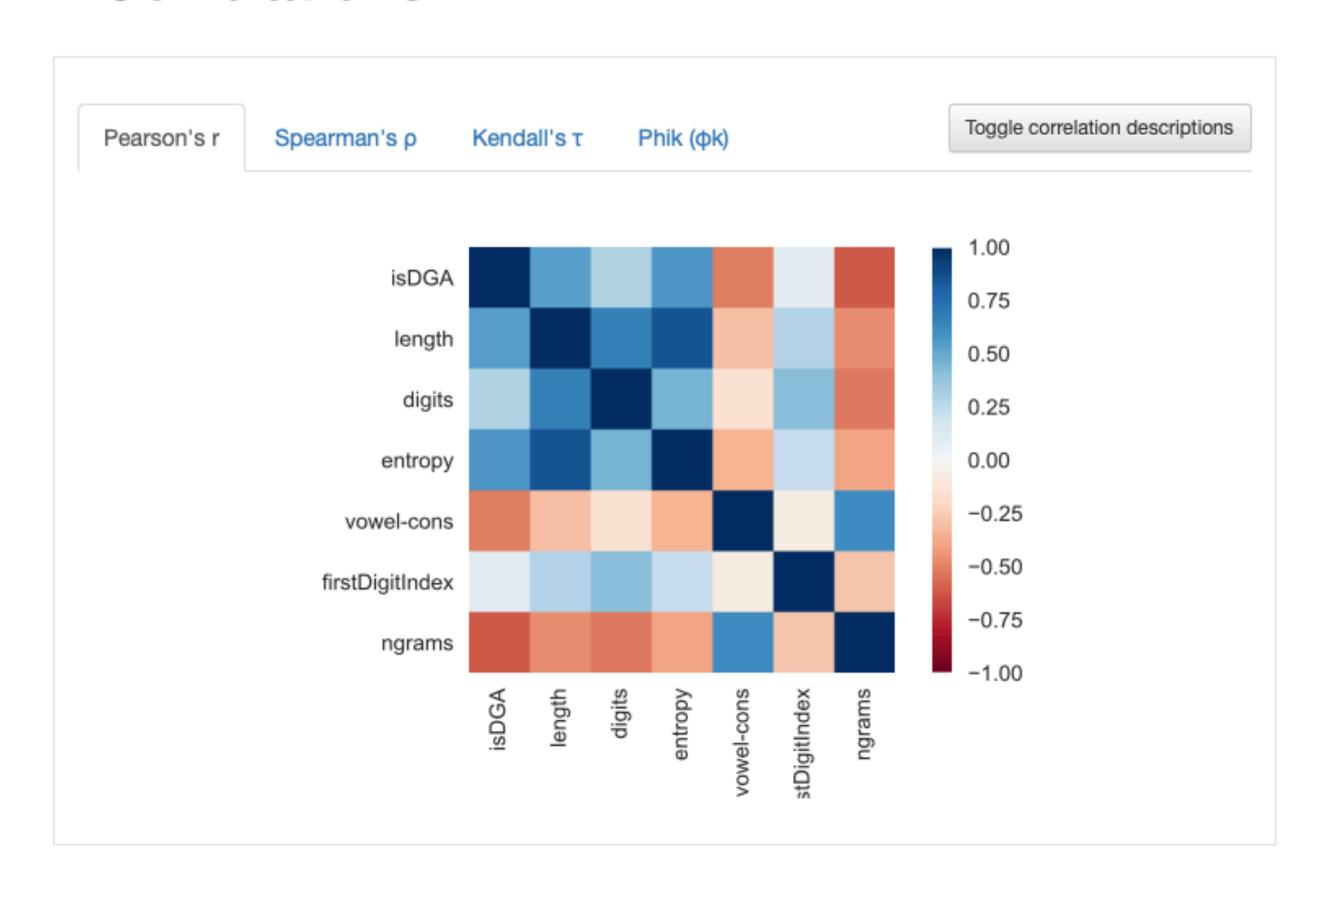

Overview

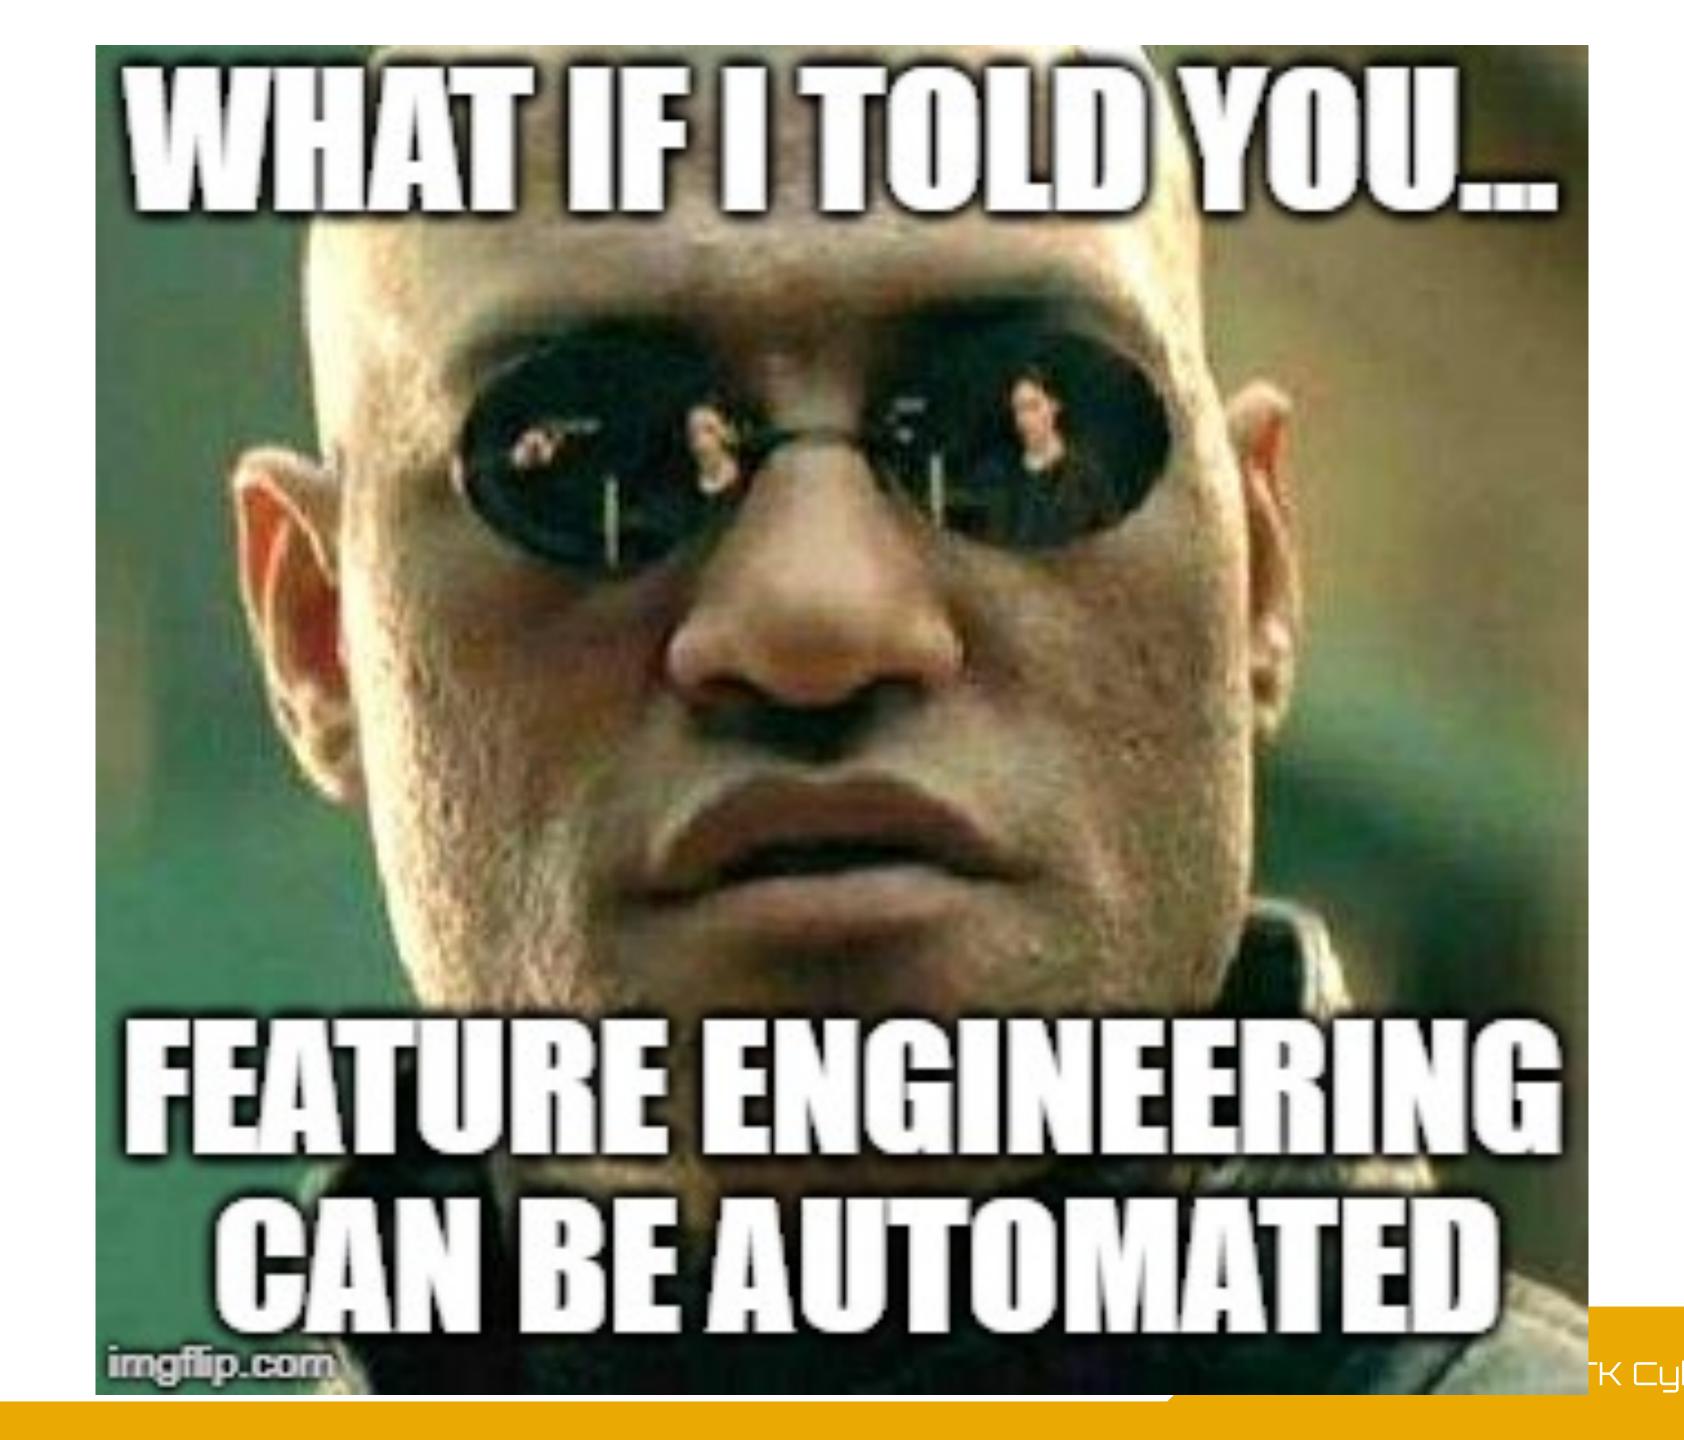

Correlations

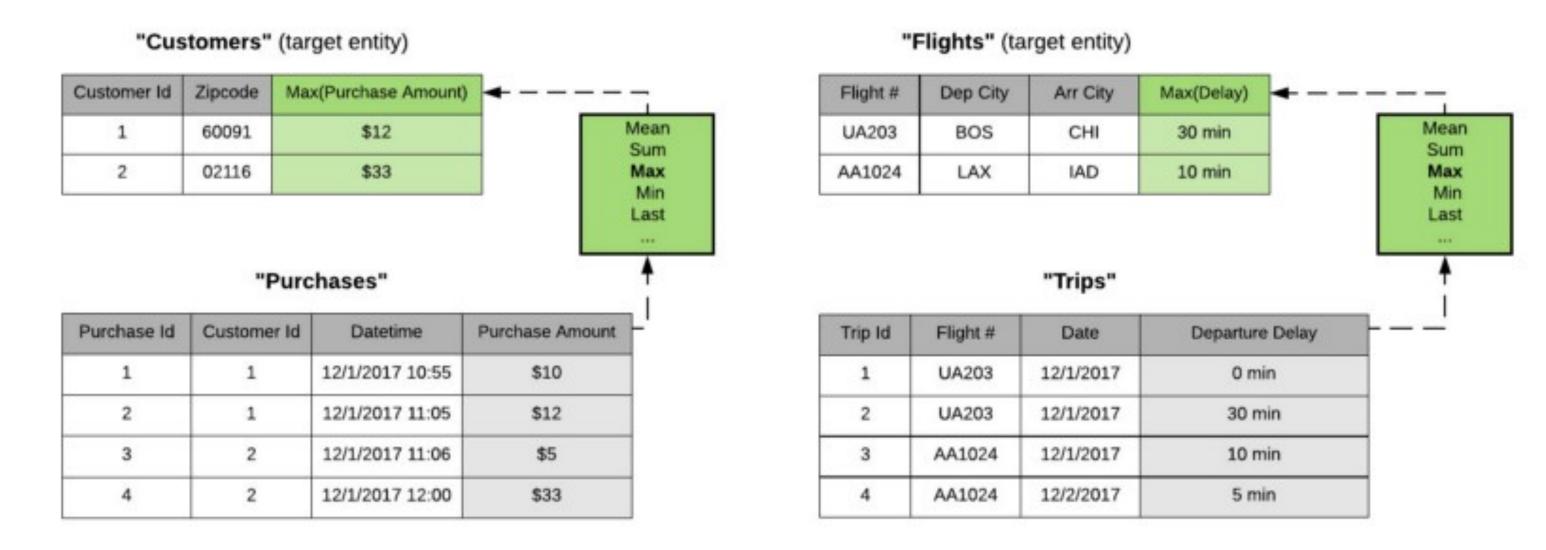

- Open Source
- Automated Feature Engineering

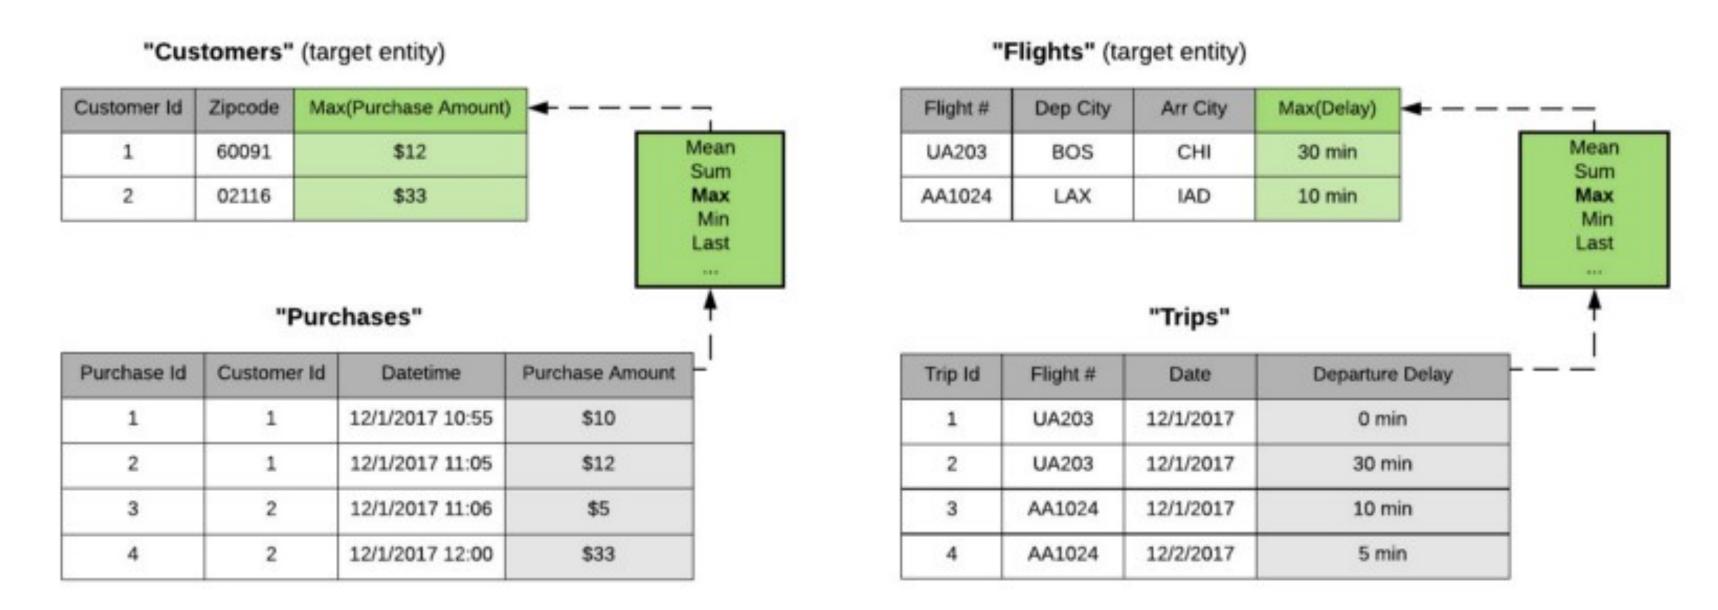

1. Features are derived from relationships between the data points in a dataset.

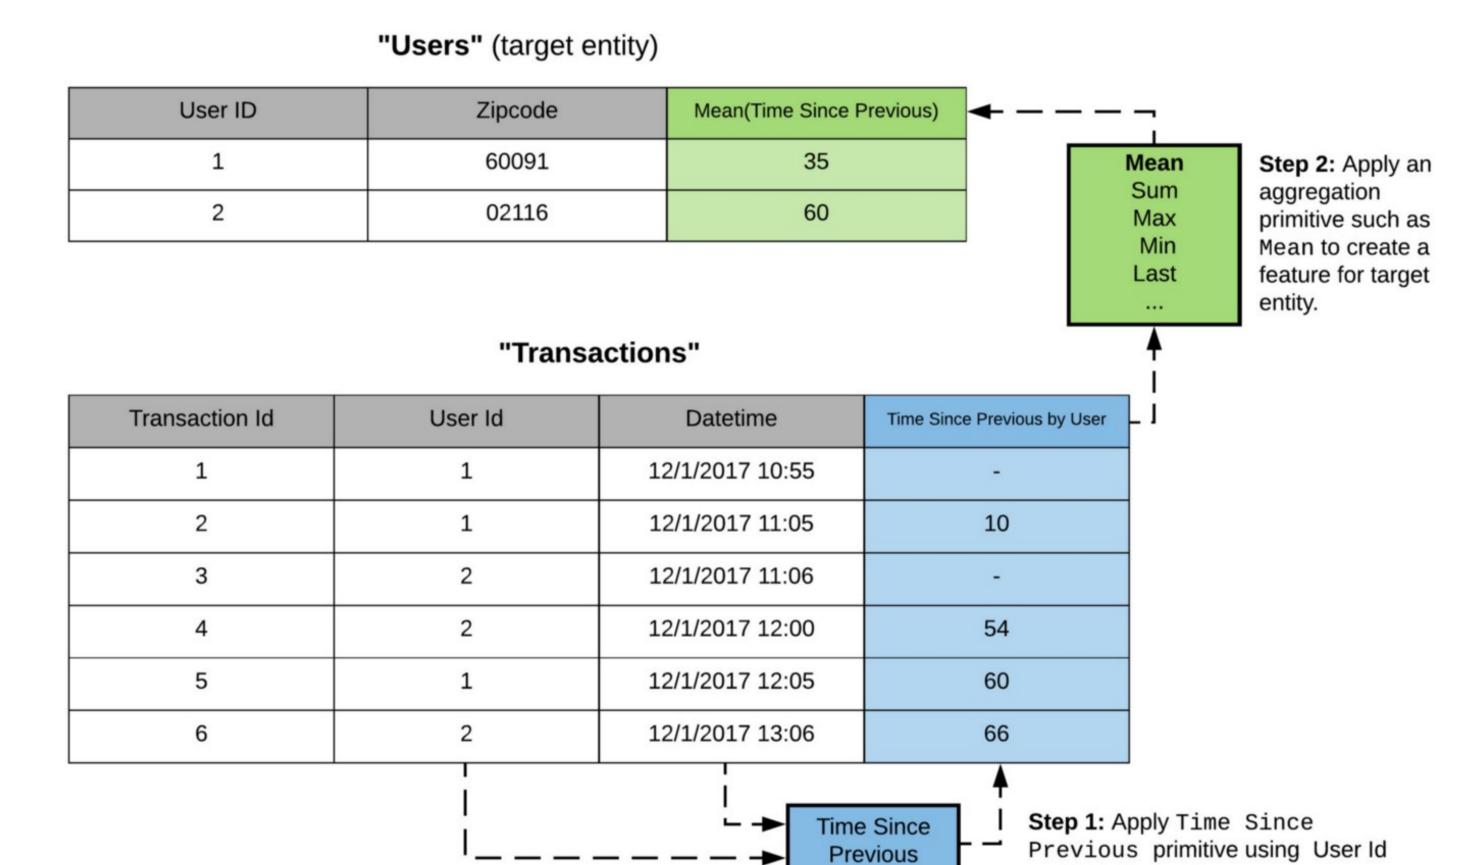

To calculate a customer's most expensive purchase, we apply the **Max** primitive to the purchase amount field in all related purchases. When we perform the same steps to a dataset of airplane flights, we calculate "the longest flight delay".

2. Across datasets, many features are derived by using similar mathematical operations.

To calculate a customer's most expensive purchase, we apply the Max primitive to the purchase amount field in all related purchases. When we perform the same steps to a dataset of airplane flights, we calculate "the longest flight delay".

3. New features are often composed from utilizing previously derived features.
